BARN REVIEWS: The LVMS8 Difference

"At Mark Sluys' dairy farm, we utilize LVMS8 for fresh cows and heifers requiring additional care, as well as for sick cows exhibiting symptoms such as decreased appetite, mastitis, or high ketosis. Over the past four years, LVMS8 has become an integral part of our farm's management protocol. Our implementation of LVMS8 includes several methods:

1. Whenever an animal receives a calcium or ASA bolus, it also receives a 60cc syringe oral dose of LVMS8.
2. LVMS8 is administered independently via pump/drench or orally. Administering LVMS8 is straightforward as animals find its taste appealing. LVMS8 significantly aids in stimulating appetite and supports animals during antibiotic treatments, helping to maintain their wellbeing and vitality."

HOW IT WORKS

The LVMS8 molecule is positively charged. This highly absorbable ion of nutrition is attracted to the negatively charged blood cells. When fed to the animal absorption takes place immediately via the digestive system and **rehydrates stressed cells** in the blood. LVMS8 helps to create a **healthy rumen environment** which helps to **improve the animals immune system**. LVMS8 also helps to keep the blood mineralized allowing your livestock to stay **calm and focused**.

"I've been using LVMS8 since February 2015 by putting it in the TMR mixer once a day, while in a tie stall barn environment.

In Dec 2022 we moved into our new robot barn, now the cows receive LVMS8 while in the robot. I'm giving my cows extra prior to calving and to the calves once they are born. I am milking less cows and improving their overall health and seeing less vet bills. I think that by starting the heifers off right and keeping them healthy, you end up with better cow at the end of the day and she will milk longer too.
